

Rapport:

Inlämningsuppgift u05-car-rental

Syfte

Uppgiften är att utveckla en applikation med hjälp av PHP, JavaScript och Twig som beskriver ett system för uthyrning av bilar. Applikation skall baseras på MVC-modellen och kommunicera via en router. Applikationens data skall lagras i en databas med hjälp av MySQL.

Jag har valt att avvika något från den struktur på uppgiften som framgått av den delade specifikationen. I stället för att ha en speciell sida för huvudmeny har jag valt att integrera denna på samtliga sidor. För mig framstår detta som betydligt mer användarvänligt då det undviker onödig navigering. Jag har också gett användaren möjlighet att ångra gjorda raderingar från kund- och biltabellerna. Tyvärr har jag inte haft tid att göra så att en sådan ändring även backar gjorda rensningar i uthyrningstabellen. För detta skulle samtliga ändrade rader behöva lagras tillfälligt för att kunna återställas. Det är inget stort problem men jag har inte gjort det.

Arkitektur

Applikationen baseras på en .htaccess fil som styr om all trafik till en och samma index.php fil. I denna index-fil skapas en instans av klassen Router som med hjälp av ett objekt av klassen Request analyserar den sökväg som angetts i URI:n. Routern bryter ner sökvägen i sina beståndsdelar vilka genom regex-mönstermatchning paras ihop med möjliga sökvägar lagrade i en separat fil. Genom att matcha sökvägen mot de fördefinierade vägarna styrs anropet till det Controller-objekt (kontrollanten) som ansvarar för denna typ av anrop och den aktuella metoden på kontrollanten anropas.

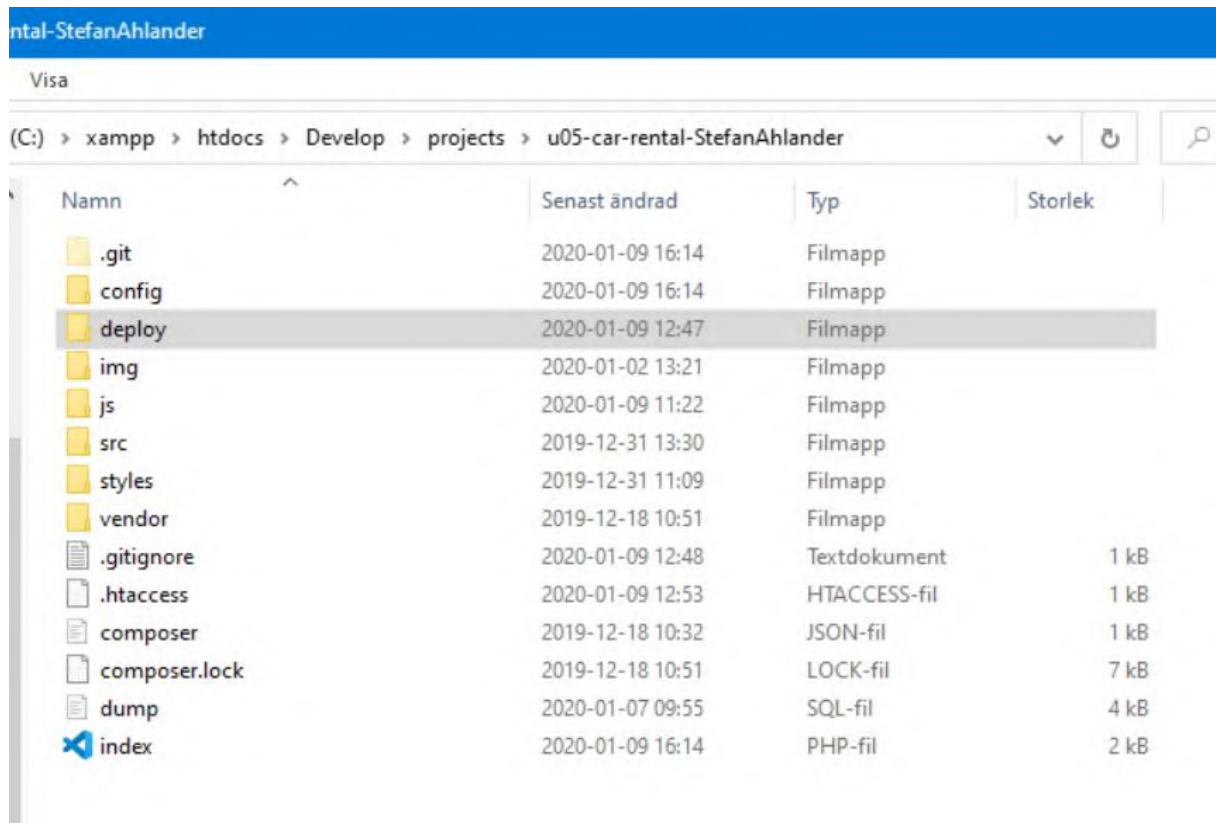

Den åberopade metoden på kontrollant-objektet ansvarar för eventuell applikationslogik och att, vid behov, kommunicera med datalagret för att därefter vidarebefordra data att presentera skärmen. Själva presentationen sker genom Twig. Kommunikationen med datalagret sker genom separata modeller som åberopas från kontrollanten.

Kontrollanterna kommunicerar, som sagt, inte direkt med databasen utan med modeller, klasser, som ansvarar för att i sin tur skriva, modifiera, ta bort och hämta data från databasen. Då de olika kontrollerna gör liknande anrop har applikationen en super-modell-klass som de andra modellerna ärver från. Det är denna superklass som ansvarar för kommunikationen med databasen medan underklasserna ansvarar för att fungera som ett interface gentemot kontrollerna. På så vis undviks repetitiv kod och genom underklasserna kan relativt komplicerade metदानrop döljas från kontrollerna.

Datalagrets modeller, vilka är egna klasser, motsvarar M (Model) i MVC-modellen. De presentationer som görs av Twig gentemot användaren motsvarar V (View) i MVC-modellen. Slutligen motsvarar kontrollanterna C (Controller).

Dokumentation

Applikationen är utförligt kommenterad vilket får tjäna som den primära dokumentationskällan. Här kommer en översiktlig genomgång av beståndsdelarna. Denna genomgång kommer att följa den befintliga mappstrukturen.

Config-mappen innehåller en config-fil med inloggningsuppgifter för databasen samt applikationens "bas-url". Bas-url används för att applikationen på min server inte ligger i rot-foldern utan i en underkatalog. I config-mappen finns även filen, routes.json, som innehåller applikationens sökvägar och som används av routern.

Deploy-mappen innehåller modifierade versioner av config-filen och routes.json-filen för den version av applikationen som ligger uppe på Internet. Dessa filer versions hanteras inte av säkerhetsskäl.

I img-mappen finns bara en bakgrundsbild som visas på startsidan.

Mappen js innehåller den Javascript fil som laddas in varje gång en ny vy visas. Javascript-koden används för att verifiera användarens input innan denna lagras i databasen.

I src mappen ligger den huvudsakliga applikationskoden och jag återkommer till denna nedan.

Styles-mappen innehåller en CSS-fil för att göra applikationen något trevligare att titta på.

Vendor mappen innehåller filer kopplade till Twig. Det är där som composer lagrar de filer eller moduler som installerats.

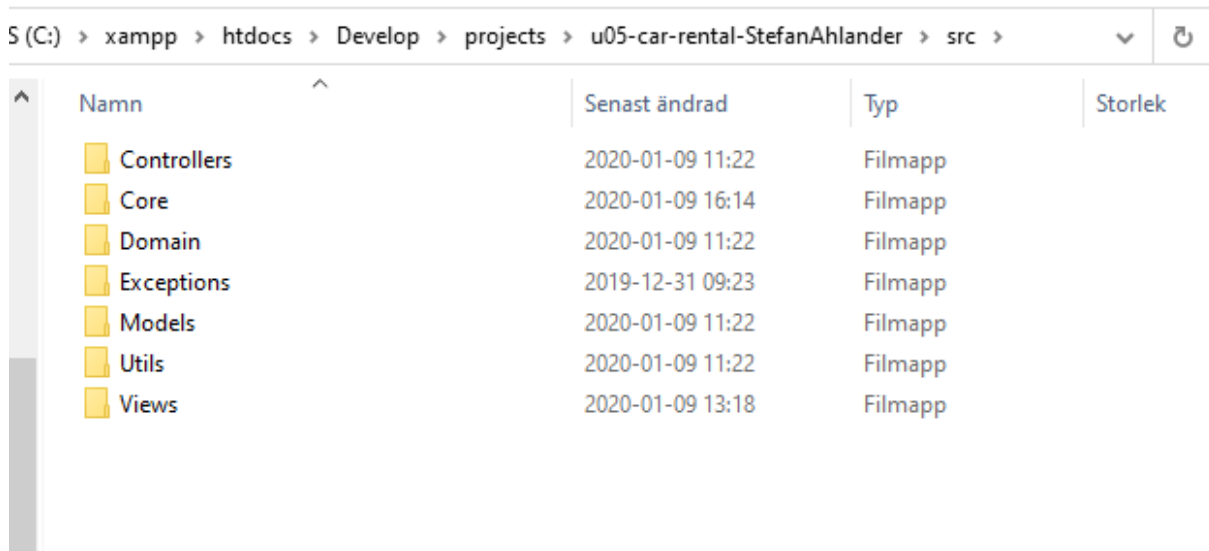

.gitignore filen används för att förhindra att "vendor"-mappen samt "deploy"-mappen versions hanteras.

Genom .htaccess filen styrs alla sidanrop om så att index.php filen körs oavsett sökväg.

Composer och composer.lock är filer som används av Composer för att hantera insticksmoduler samt den autoloader som används för applikationen.

Dump.sql filen innehåller de kommandon som "bygger" den ursprungliga databasen som används av applikationen.

Slutligen är index.php applikationens hjärta, den fil som hanterar hela applikationen.

Namn	Senast ändrad	Typ	Storlek
Controllers	2020-01-09 11:22	Filmapp	
Core	2020-01-09 16:14	Filmapp	
Domain	2020-01-09 11:22	Filmapp	
Exceptions	2019-12-31 09:23	Filmapp	
Models	2020-01-09 11:22	Filmapp	
Utils	2020-01-09 11:22	Filmapp	
Views	2020-01-09 13:18	Filmapp	

Src-mappen har flera mappar som innehåller de olika delarna av applikationen.

Controllers, Models och Views är ganska självförklarande.

Core-mappen innehåller filer som är gemensamma för applikationen. Där finns Config-klassen som används för att ta fram data ur config-filen. Där finns också en hjälp-klass, FilteredMap, som används för att "tvätta" information som lämnas av användaren innan denna läggs in i databasen. Detta för att försöka minska risken för angrepp genom så kallad SQL-injection. I mappen finns också klasserna Request och Router som ansvarar för att styra användaren rätt i applikationen genom att analysera de angivna sökvägarna.

Mappen domain innehåller klasser som beskriver de objekt som applikationen använder sig av. Bilar, kunder och uthyrningar. Det är dessa objekt som skapas, modifieras, tas bort och lagras i databasen.

Exceptions innehåller klasser för att kunna avgöra vilka typer av fel som inträffar när applikationen används.

I mappen Utils slutligen så ligger den klass, DependencyInjector, som används för att skicka runt applikationsberoenden utan att behöva lista separata beroenden för de olika delarna av applikationen.

Exempel på exekvering

När en användare navigerar till applikationen kommer denne att genom .htaccess filen dirigeras till filen index.php. När denna efterfrågas på servern kommer php-skriptet att köras.

I index-filen görs flera saker. Applikationen konfigureras och därefter analyseras den angivna sökvägen och genom routern åberopas "rätt" kod utifrån angiven sökväg.

Om användaren exempelvis har navigerat till sökvägen "/customer" kommer denna att matchas mot de tillåtna sökvägarna i routes.json-filen. Utifrån denna matchning kommer routern att skapa en instans av klassen "CustomerController" och sedan åberopa dennes getAll-metod.

"CustomerController" ärver egenskaper och metoder av klassen "ParentController".

Metoden getAll kommer i sin tur att skapa en instans av klassen "CustomerModel".

"CustomerModel" har flera metoder för att hantera data. Då många av de operationer som "CustomerModel" utför har sin motsvarighet i "CarModel" har den kod som faktiskt kommunicerar med databasen brutits ut och finns i klassen "DataModel" som de övriga "..Model" klasserna ärver från.

"CustomerModel" kommer att i sin tur att förbereda en fråga eller ett statement och sedan åberopa en av de metoder på "DataModel" som direkt kommunicerar med databasen. Genom att dela upp koden på detta vis undviks repetition. "CustomerModel" kommer att returnera det svar denne får från "DataModel" till "CustomerController".

När "CustomerController" kommer att skicka denna information vidare till Twig som använder sig av denna och en template för att skapa den HTML-kod som returneras av servern till användaren.

Databasen

Databasen är en MySQL databas och innehåller fem tabeller. En för data relaterat till kunder, en för bilar, en för uthyrningar och två för bilars möjliga märken och färger.

Ett problem jag haft relaterat till databasen är hur informationen från de olika tabellerna ska sammanfogas. Ett sätt innebär att data lagras dubbelt i olika tabeller men detta strider mot normaliseringsreglerna för SQL-databaser.

Samtidigt är ett av kraven för applikationen att den ska kunna visa när en viss användare som för tillfället hyr en bil checkat ut denna. Jag har inte lyckats få till en fråga som kan visa detta utan att samma data visas för kunder som tidigare hyrt bilar.

Frågan:

```
SELECT customers.personnumber, name, address, postaladdress, phonenumber, checkouttime FROM customers LEFT JOIN rentals ON customers.personnumber = rentals.personnumber WHERE checkouttime IS NOT NULL AND checkintime IS NULL
```

Ger mig alla kunder som just nu hyr en bil.

Frågan:

```
SELECT customers.personnumber, name, address, postaladdress, phonenumber, checkouttime FROM customers LEFT JOIN rentals ON customers.personnumber = rentals.personnumber WHERE (checkouttime IS NOT NULL AND checkintime IS NULL) OR checkouttime IS NULL
```

Ger mig alla kunder som aldrig hyrt någon bil plus de som just nu hyr.

Frågan:

```
SELECT * FROM customers WHERE personnumber NOT IN (SELECT personnumber FROM rentals WHERE checkouttime IS NOT NULL AND checkintime IS NULL);
```

Ger mig i sin tur alla kunder som just nu inte hyr någon bil.

Någon fråga som visar NULL i kolumnen för "checkedouttime" för bilar som varit uthyrda tidigare men som inte nu är det har jag inte lyckats klura ut.

I stället har jag gjort så att jag ställt två frågor till databasen, alla kunder och alla kunder som just nu hyr en bil, och kombinerat svaren i den aktuella "Controller" som använts, innan informationen levererats vidare till Twig.

Exempelkod

Följande sidor innehåller kodexempel ur applikationen. Exempler är ett urval av vad jag ansett viktigast att visa upp. Övrig kod finns på GitHub och är kommenterad på liknande vis.

Då jag anser att koden är utförligt kommenterad och då jag försökt använda beskrivande namn på variabler, metoder och klasser kommer jag inte att gå in närmare på den här.
